The techno-economic potential of integrated gasification 
co-generation facilities with CCS

Going from coal to biomass

Abstract

This study analyses the impact of technological improvements and increased operating experience on the 
techno-economic performance of integrated gasification facilities producing electricity and/or transportation fuels. 
Also, the impact of using torrefied biomass instead of coal and/or applying CCS is examined. Results indicate that 
current production costs of electricity and/or transportation fuels are above market prices. Future improvements, 
however, could reduce production costs sufficiently to make gasification facilities economical. Furthermore, although 
CCS can be used to reduce CO₂ emissions at relative low CO₂ avoidance costs, only the use of biomass allows the 
production of carbon neutral electricity and/or transportation fuels and in combination with CCS can even result in 
negative CO₂ emissions.

1. Introduction

To significantly reduce global CO₂ emissions requires the decarbonisation of both the transport and 
power sector [1]. Integrated gasification (IG) facilities producing electricity or Fischer-Tropsch liquids 
(FT-liquids) can potentially decarbonise both sectors by applying carbon capture and storage (CCS) 
and/or using biomass as feedstock. Being able to use biomass as well as coal means that these facilities 
can play a role in the transition towards a renewables based energy infrastructure.

In previous research we examined the technical and economic potential of state-of-the-art (SOTA) 
integrated gasification poly-generation (IG-PG) facilities [2,3]. Our results show that coal and biomass
can be converted into electricity at 38-40% efficiency\(^1\) and FT-liquids at 55-60% efficiency. Using torrefied wood pellets (TOPS) results in improved technical and economic performance compared to conventional wood pellets. Also, it was shown that with SOTA technology neither electricity nor FT-liquids can be produced competitively. Advanced technologies and technological learning can, however, bring production costs down. This may make integrated gasification facilities profitable in the longer term. Therefore, in this study the impact of potential technological and operational improvements on the technical and economic performance of integrated gasification facilities is assessed.

#### 1.1. Integrated gasification facilities

In an IG facility (Figure 1), a solid carbon-containing feedstock is fed into an entrained flow (EF) gasifier. The high operating temperatures (>1500°C) result in a syngas consisting mainly of CO, CO\(_2\), H\(_2\) and H\(_2\)O. The required heat is supplied by combusting part of the feedstock by adding a sub-stoichiometric amount of oxygen, supplied by an air separation unit (ASU). Pure oxygen instead of air is used to obtain the required high temperatures, to increase overall efficiency and to reduce the size of downstream equipment [4,5]. The syngas is cooled and cleaned of contamindates. Depending on the desired product, the H\(_2\):CO ratio of the syngas is adjusted in a water-gas shift (WGS) reactor. This can be done before or after the acid gas removal (AGR). When producing electricity, the syngas is fed into a gas turbine and combusted. When producing FT-liquids, the syngas is fed into a FT-reactor. The FT-liquids are purified and any off-gas is fed into a gas turbine and combusted. To increase the overall economics of an IG facility, steam is generated at various locations and used for electricity production in steam

turbines. To lower the CO\textsubscript{2} emissions of the facility, CO\textsubscript{2} can be captured at the AGR, compressed and subsequently stored in underground geological reservoirs. Detailed information of the individual components, i.e., ASU, gas cleanup, gas and steam turbines, can be found in Meerman et al., [6].

Waste, heat and recycle streams are not displayed [2].

2. Methodology

Based on commercially available technologies, plant configurations for SOTA IGCC and IG-FT facilities, both with CO\textsubscript{2} capture and storage (CCS) and without (Vent), were selected [6]. The time period in which new technologies are expected to become commercially available was selected based on the following criteria:

- Short term (2015-2020): technologies that are currently being tested in large-scale pilot projects;
- Mid term (2020-2035): technologies that have been successfully tested in laboratories and/or that are being tested in small scale pilot projects;
- Long term (2035-2050): technologies that are currently under development at lab scale or are at proof-of-concept stage.

When multiple technologies are available for the same process, the technology with the lowest production costs of the main product was selected. The resulting configurations were modelled in a component-based chemical AspenPlus simulation model [2]. This model calculates the relevant mass- and energy balances and, combined with an Excel-based economic model, allows the calculation of the production costs [2,3,6].

Production costs of the main product were calculated using the net present value (NPV) method, see equation (1) [7]. Note that temporary stored carbon in the chemical products still counts as emitted CO\textsubscript{2}. To include transport and storage of CO\textsubscript{2}, a fixed price per t CO\textsubscript{2} was taken. CO\textsubscript{2} avoidance costs were calculated according to equation (2). All cost data are given in €\textsubscript{2008}. Common technical and economic parameters are presented in Table 1.

\[
P_{\text{MP}} (€/GJ) = \frac{\alpha \times (I + \text{O&M} + \text{Feedstock}) - \sum (F_{\text{SPx}} \times P_{\text{SPx}})}{F_{\text{MP}}} 
\]

\[
\text{CO}_2 \text{ avoidance costs (€/t CO}_2) = \frac{P_{\text{MP,ref}} \times P_{\text{MP,REF}}}{(E_{\text{ref}} / F_{\text{MP,ref}}) \times (E / F_{\text{MP}})} 
\]
Where $\alpha$ is capital recovery factor (yr$^{-1}$), calculated by $r/(1-(1+r)^{-L})$; $r$ is discount rate; $L$ is economic lifetime (yr); $I$ is total capital investments of the facility (M€); O&M is operating and maintenance costs (M€/yr); Feedstock is coal or TOPS cost (M€/yr); $F_{SPx}$ is annual flow side-product x (GJ/yr or kt/yr); $P_{SPx}$ is market price of side-product x (€/GJ or €/kt); $F_{MP}$ is annual flow of main product (GJ/yr); $P_{MP}$ is production costs of main product (€/GJ); $E$ is net CO$_2$ emission, including carbon in chemical products (t CO$_2$/yr); Ref is the reference system, namely a coal-fired integrated gasification facility without CCS.

1) Based on literature, a construction time of three years was assumed and capital costs were evenly divided over these years [5,8,9,10].
2) The O&M costs are assumed to be 4% for all components except if stated differently in literature.
3) Feedstock costs were 2.25 €/GJ for coal and 6.3 €/GJ for biomass pellets beginning 2010. Although TOPS are not produced commercially today, it was assumed that they have the same price as biomass pellets as the increase in production costs is compensated by reduction in transportation costs. Literature studies show that TOPS prices could drop to 3 €/GJ TOPS [11,12,13,14,15]. See Meerman et al., for more information [3].
4) According to the Zero Emission Platform, transport to and storage in depleted gas or oil fields of CO$_2$ will cost between 2-15.7 €/t CO$_2$. When storing offshore, the CO$_2$ transport and storage costs increase to 5.5-20 €/t CO$_2$ for depleted gas or oil fields [16]. Based on expert interview, the CO$_2$ transport and storage costs were set at 10 €/t CO$_2$ [17].
5) The reference electricity price is based on the average Dutch day-hourly market price between 2004-2008. The observed trends were considered representative for NW-Europe. During that period the electricity price varied between 0-1050 €/MWh (0-290 €/GJ), with an average price of 57 €/MWh (15.7 €/GJ) [18].
6) In this study CO$_2$ avoidance costs are calculated. Therefore, no CO$_2$ credit price was used.

3. Results

3.1. Configurations

Based on commercial technologies and expected technological development, the following configurations for the IGCC and IG-FT facilities were made (see Table 2).

ASU: air separating unit; ITM: ion transfer membrane; TDS: transport desulphurisation; DSRP: direct sulphur recovery plant; WGS: water-gas shift; SEWGS: sorption enhanced water-gas shift; GT: gas turbine; SOFC: solid oxide fuel cell; HRSG: heat recovery steam generation; IP: intermediate pressure; HP: high pressure; N.A: not applicable.

The current configurations consist of cryogenic ASU, lock-hopper feeding system, dry-fed Shell EF gasifier, candle filter, wet scrubber, WGS reactor (for CO₂ capture or FT-liquids production), solvent based AGR (Selexol for IGCC or Rectisol for IG-FT), Claus/SCOT, FT-reactor with conventional FT-catalysts (only for IG-FT) and SOTA gas and three pressure steam turbines. If CO₂ is captured, the integrated gasification facilities also contain a conventional CO₂ compressor.

In the short term, only gradual improvements to already existing technologies are expected. The improved technologies are cryogenic ASU, solvent-based AGR and the gas turbine.

In the mid term several new technologies can be introduced which require alterations in the overall process configurations compared to SOTA. Common to both facilities is the replacement of the cryogenic ASU with an ion transfer membrane ASU. The lock-hopper is replaced by a solid feed pump and the gas turbine is upgraded to a high efficiency design. If CO₂ is compressed, the CO₂ compressor is replaced by a RamGen compressor. IGCC facilities can be equipped with hot gas cleaning and transport desulphurisation. The sulphur compounds are converted into elemental sulphur using the direct sulphur removal process, thereby eliminating the need for the Claus and SCOT installations. In the case of IGCC-CCS, the syngas is shifted using SEWGS after the sulphur compounds are removed. SEWGS also removes CO₂ from the syngas. A problem is that the H₂:CO ratio cannot be manipulated while still obtaining a low CO₂ concentration in the syngas. As the FT-reactor requires a certain H₂:CO ratio as well as a low CO₂ concentration, SEWGS cannot be used. Therefore, the IG-FT facilities will still rely on a separate WGS and CO₂ removal units. The WGS is upgraded to reduce the steam consumption and the Rectisol AGR is improved, resulting in reduced energy consumption.

In the long term, the operation conditions of the steam cycle could change from subcritical to supercritical. Also, the syngas cooler is expected to be upgraded to produce high pressure steam instead of intermediate pressure steam. The Rectisol based AGR in the IG-FT facilities is improved even further. The catalyst in the FT-reactors is replaced by a diesel selective catalyst with a different chain growth probability (α) depending on the length of the hydrocarbon. It is assumed that this has no effect on the reactor size and costs. The gas turbine is improved even further.
3.2. Integrated gasification facility performance

Currently, both the IGCC and IG-FT facilities have production costs above the market price of the main product (see Figure 2). Advancement in technologies, however, can make them profitable. In the long term, the efficiency of a coal-fired IGCC without CCS could increase from 44% to 52%, while production costs drop from 17 €/GJ (60 €/MWh) to 11 €/GJ (40 €/MWh). The increase in efficiency is mainly due to a higher output of the gas turbine. Production costs are affected by an increase in efficiency (-2.4 €/GJ) and availability (-1.7 €/GJ) and reduction in capital and O&M costs (-1.4 €/GJ). If SOFCs are used, the efficiency could increase to 59%, but the high capital and O&M costs of the SOFC increase production costs to 13 €/GJ (45 €/MWh). Applying CCS in the long term could result in an efficiency of 43% and production costs of 16 €/GJ. Compared to SOTA facilities, the energy consumption of the CO2-capture equipment decreases, but energy demand of the CO2 compressor increases as the CO2 exiting the SEWGS is at a low pressure. Despite the higher energy penalty, this system was selected as the capital costs of a facility using SEWGS is much lower than if a solvent-based CO2 capture system is used, resulting in lowest production costs for the SEWGS system. An IGCC equipped with CCS could have lower production costs if SOFCs become available. Although capital costs increase by 13%, overall energetic efficiency increase by 13%, resulting in production costs of 14 €/GJ.

Figure 2 Production costs of electricity (above) and FT-liquids (below). The lighter upper part of the feedstock bar is the addition in production costs when using the high value for the TOPS price.
FT-liquids can currently be produced from coal for 13 €/GJ, which is competitive with crude oil derived fuels at an oil price of 113 $/bbl. In the long term, overall energetic efficiency could increase from 61% to 65%. The higher efficiency, lower capital costs and increased availability could reduce produce costs to 9 €/GJ. Applying CCS at a SOTA coal-fired IG-FT would result in an efficiency of 58% and production costs of 15 €/GJ. In the long term, the efficiency could increase to 63% and production costs could drop to 10 €/GJ.

3.3. CO₂ emissions

The CO₂ emissions of the SOTA coal-fired IG facilities are around 2,000 kt CO₂/yr, which could increase to 2,400 kt CO₂/yr due to a higher availability. For electricity this means specific emissions of 0.7 kg CO₂/kWh. As overall energetic efficiency is expected to increase over time, this value could drop to 0.5 kg CO₂/kWh in the long term. For FT-liquids, the specific emissions are around 0.2 t CO₂/GJFT-liquids both now and in the long term. If CCS is applied, specific emission of the IGCC facility are currently 0.03 kg CO₂/kWh and could drop to 0.01 kg CO₂/kWh in the long term. The production of FT-liquids while applying CCS shows a different picture. As a significant fraction of the carbon is embedded in the end product, specific emissions are 0.1 t CO₂/GJ, both now and in the long term.

In order to produce carbon-neutral electricity or transportation fuels, the use of biomass is mandatory. If only TOPS is used and CCS is not applied, specific CO₂ emissions are zero, regardless of production. If, however, TOPS and CCS are combined, specific emissions of electricity production are -0.9 kg CO₂/kWh for SOTA installations and could change to -0.6 kg CO₂/kWh in the long term. The increase in specific emissions is due to the higher efficiency, meaning that for the same amount of electricity, less biomass is needed and less CO₂ can be stored. The specific emissions of TOPS-based FT-liquids while applying CCS are around -0.1 t CO₂/GJ.

3.4. Effect of a CO₂ price

The effect of a CO₂ price on the production costs of SOTA IGCC and IG-FT facilities is given in Figure 3. The impact of the biomass price on the production costs is clearly visible. The main difference between the IGCC and IG-FT facilities is the penalty of applying CCS. For the IGCC facilities, CCS becomes attractive only at higher biomass (>6 €/GJ) and/or CO₂ prices (>25 €/t CO₂). For IG-FT facilities CCS is already attractive at low CO₂ prices (>10 €/t CO₂), even if biomass prices are low (>3 €/GJ). The results also indicate that at moderate CO₂ prices (>30-40 €/t CO₂, depending on the biomass price) the combination biomass and TOPS results in the lowest production costs.

![Figure 3 Effect CO₂ credit price on production costs of SOTA integrated gasification facilities. The shaded area is the range due to low and high TOPS prices.](image-url)
4. Conclusion

Advanced technologies may reduce production costs of a coal-fired IGCC without CO₂ capture from 17 €/GJ to 11 €/GJ. When CO₂ is captured, it is found that production costs are lowered from 23 €/GJ to 14 €/GJ using SOFC. This would result in IGCC becoming profitable in the short term if CCS is not applied and in the long term if CCS is applied. When TOPS are used as feedstock, production costs are currently calculated at 25 €/GJ without CCS and 35 €/GJ with CCS, dropping to respectively 19 €/GJ and 21 €/GJ in the long term. New technologies alone do not lower production costs of TOPS-fired IGCC under the current average electricity market value of 16 €/GJ. If, as several studies indicate, TOPS prices drop to 3 €/GJ, production costs would decrease to 12 €/GJ without CCS and 15 €/GJ with CCS in the long term. In this case, production costs would drop under the current market price.

New technologies in IG-FT facilities are found to have a slightly smaller impact on the production costs. When using coal, production costs decrease from 13 €/GJ to 9.1 €/GJ if CO₂ is vented and from 15 €/GJ to 10 €/GJ if CO₂ is captured and stored. The use of TOPS would result in 23 €/GJ and 18 €/GJ without CCS and 24 €/GJ and 19 €/GJ with CCS for respectively now and in the long term. Here, lower biomass feedstock costs of 3 €/GJ results in production costs of 11 €/GJ without CCS and 12 €/GJ with CCS.

Specific CO₂ emissions can be reduced by capturing CO₂ or by substituting coal by TOPS. If both options are applied, net negative emissions can be obtained. This option becomes attractive both for IGCC and IG-FT facilities at moderate CO₂ prices (>30-40 €/t CO₂).

It is concluded that gasification can be an attractive technology to produce carbon neutral electricity and/or transportation fuels. Although production costs are currently above market prices, future improvements can lower the production costs and make gasification facilities profitable. Furthermore, both biomass and CCS can be used to reduce CO₂ emissions at relative low CO₂ avoidance costs.
